

→ Statistics is the branch of the mathematics that involves, collecting, analyzing, interpreting and drawing conclusion from data and informations. So in simple, whatever you will apply functions on data for getting conclusions or information, in this we use statistics. Different different functions like mean, median, mode, descriptive statistics, or inferential and so on.

→ Types of statistics:

- 1. Descriptive
- 2. Inferential

✓ Descriptive statistics: with which involves collecting, collection, analyzing and interpretation of data, its primary goal is to understand the main feature of the data.

In this type we will get such functions which will help us to understand the data.

So this is the first step whenever we are performing any kind of data analysis the first step is to performing the descriptive statistics.

So we can say this organizing and summarizing.

It also involves different types of graphs and tables; for using this we can easily understand the data, and we can easily visualize its distribution. It also involves descriptive

measures, like, average, variations, percentile etc.

So desc statistics is all about to understand the data set. and on the basis of

understand what analysis you are performing on your data. this thing we can decide.

2, Inferential statistics is drawing conclusion from data. and word Data represent complete population.

Population:- is complete entire population, so if we need any conclusion of entire population then we are not able to study entire population.

so in population we take/use small sample / subset to whom we say sample.

so by using sample what we find conclusion is known as or come under the inferential statistics

Population
↓
Sample

→ so we ~~know~~ ^{understand} we are not able to find the whole population. so we take sample like from the 100 people we take 10 peoples as a sample. and if we will calculate their height and whatever the average height become those 10 students, then we will consider ~~at the~~ remaining 100's would have average same height.

so this was the concept of inferential statistics.

→ So whenever we get data we use descriptive statistic to understand the data.

and base on that summary we use inferential methods we choose of inferential on particular data set

— but before descriptive statistics, we must know the type of data.

→ Data = raw, facts, and figures
